Introduction

The Truven Health MarketScan® Research Databases are a family of research data sets that fully integrate de-identified patient-level health data (medical, drug and dental), productivity (workplace absence, short- and long-term disability, and workers’ compensation), laboratory results, health risk assessments (HRAs), hospital discharges and electronic medical records (EMRs) into data sets available for healthcare research. Data are contributed by large employers, managed care organizations, hospitals, EMR providers, Medicare and Medicaid.

This white paper describes the features and uses of MarketScan Research Databases from Truven Health Analytics®, part of the IBM Watson Health™ business, for life sciences research. Specifically, the paper illustrates the unique attributes of individual MarketScan databases, explains how these databases are constructed, describes their uses and highlights examples of published studies based on MarketScan data.

Filling a data need: Origins of the MarketScan Research Databases

In response to rising costs, fundamental changes occurred in the US healthcare system in the late 1980s as healthcare delivery shifted toward managed care arrangements. At the same time, there was growing interest in greater accountability for care through quality improvement. Stakeholders sought data on how these changes impacted costs, quality of care, health outcomes and cost-effectiveness. As the purchasers and payers for the privately insured segment of the US population, employers and health plan administrators were interested in accurate and timely information on the drivers of cost growth and the returns on investment for initiatives to improve employee health and well-being. Healthcare policymakers and practitioners were interested in the prevalence, incidence and costs of specific diseases, as well as the effectiveness and cost implications of interventions, clinical guidelines and quality improvement initiatives. Providers, healthcare facilities and life sciences companies were interested in the cost-effectiveness of different therapies in real-world clinical care.

At the time, data sources to support these analyses were inadequate. Importantly, there was a lack of reliable healthcare data on privately insured patients and their families. This group continues to comprise the largest segment of US healthcare users—nearly half of the total US population (see Figure 1).
Truven Health created the MarketScan data warehouse to address the need for better healthcare data on privately insured Americans. Since its creation, this warehouse has evolved into a suite of proprietary databases that contain one of the longest-running and largest collection of privately and publicly insured, de-identified patient data in the United States. MarketScan claims data reflect the real world of treatment patterns and costs by tracking millions of patients as they travel through the healthcare system; therefore, they offer researchers detailed information about all aspects of care. Data from individual patients are integrated from providers of care, and healthcare utilization and cost record connections are maintained at the patient level.

Over the years, the original claims-centric databases have been enriched and integrated with the addition of absence, disability, workers’ compensation, health risk, lab, dental, EMR, hospital and mortality data.

Unique features of MarketScan claims data

MarketScan claims databases offer several distinct advantages over other data sources.

**Very large sample size allows for research on unique patient populations**

The MarketScan claims databases offer one of the largest convenience samples available in proprietary US databases—with nearly 240 million unique patients since 1995. In the most recent full data year, MarketScan claims databases contain healthcare data for more than 43.6 million covered lives and are large enough to allow creation of a nationally representative data sample of Americans with employer-provided health insurance. The size of the databases helps to maintain analytically sufficient cohort sizes when deep segmentation of patients is required, particularly for orphan diseases.
Complete episodes of care support more inclusive cost and treatment studies

MarketScan claims databases capture the full continuum of care: physician office visits; hospital stays; retail, mail order, and specialty pharmacies; and carve-out care, such as mental health services. The importance of complete episodes of care is illustrated by the following cost offset case study.

Case study: Cost offset in treating depression

Establishing the value of a medication based on total healthcare costs as opposed to the direct cost of medication alone can be critical to assessing cost-effectiveness. Why? Because a more expensive drug therapy may produce better overall health outcomes and ultimately reduce long-term medical costs. The study illustrated in Figure 2 compared the cost of two different prescription therapies for treating depression: selective serotonin reuptake inhibitors (SSRIs) and tricyclic antidepressants (TCAs). MarketScan data revealed that the 2-year average prescription cost of TCAs was lower, but the overall cost of treatment using TCAs was higher. This demonstrated that although drug costs may be lower, it is important to look at overall healthcare costs when evaluating the cost-effectiveness of a drug treatment.

Figure 2. Managing populations: Cost offset for treating depression with SSRIs versus TCAs

**Linked data can enhance research in many disease areas**

Truven Health has the ability to link healthcare data from a variety of sources.

- Linking hospital discharge records with claims data at the patient level can fill the gap in a patient’s drug therapy between inpatient and outpatient settings.
- EMRs, when linked with claims data, can add significant clinical richness to the healthcare history of patients.
- Lab results can assist in studies of diseases such as diabetes, where HbA1c is a critical indicator of treatment outcome.
- Indirect cost research can be conducted because MarketScan claims come predominantly from employers that also provide data on absenteeism, disability and workers’ compensation, all linked to the corresponding employee’s claims.
- Linked mortality data can be essential for research in disease areas such as oncology.
- Unique to Truven Health are medical data linked to dental claims, allowing research in the area of cardiovascular disease and its relationship to oral health, for example.
- Life sciences customers have also asked Truven Health to undertake unique linking projects between MarketScan data and registry and in-house customer data. Our white paper, “Examining the patient journey: Case studies using linked health insurance claims and clinical data,” discusses this in more detail.

The following Truven Health white papers and research briefs illustrate in more detail the linking strength of the MarketScan Databases.

- **Examining the patient journey: Case studies using linked health insurance claims and clinical data**
- **The value of understanding health and productivity costs**
- **Linking health plan formulary data with MarketScan claims**

**Detailed prescription drug information**

The MarketScan claims databases contain comprehensive information on outpatient prescriptions. Through the MarketScan Early View Data Set, data are available within 45 days of the end of the service month, with monthly or quarterly updates. The MarketScan claims databases may afford distinct advantages over others that track only prescription fills. MarketScan data allow identification of the type of disease from medical claims, and they can be used to determine whether clinical, demographic and/or provider characteristics influence prescribing patterns.
Prescription fills for individual patients are recorded so that therapies prescribed concurrently—and presumably used in combination—can also be identified. This provides vital information about actual drug use patterns, as opposed to individual drug prescription trends.

The MarketScan Hospital Drug Database provides researchers with inpatient drug utilization data from hospital discharge records. These data allow researchers to understand drug use in the inpatient and outpatient settings, including hospital use patterns, switching behavior, combination therapy and patient characteristics. This information can be used to determine if introduction or early use of a product would improve clinical and overall cost outcomes. These data can also be used to analyze diagnosis volumes. When researchers need to understand the impact of a hospitalization on prescription drug use, the MarketScan Inpatient Drug Link File links outpatient data from claims with inpatient drug data from the Hospital Drug Database, enabling this analysis.

**High-quality coding**

We believe an advantage of MarketScan claims data involves comprehensive and high-quality coding. Key examples include:

- Fully paid and adjudicated claims
- Complete payment or charge information, including the amount that is the patient’s responsibility
- Complete outpatient prescription drug information, including patient copayments, mail order prescriptions, information about injectable treatments, data from specialty pharmacies and carve-out services, manual and electronically submitted claims, and plan or formulary summaries

**Numerous and widely published research applications**

MarketScan-based research has made a contribution to the body of literature used to formulate policy decisions and improve healthcare for Americans. The first publication appeared in 1990 in the *New England Journal of Medicine* (J.B. Hillman, et al.). Since then, more than 1,100 articles have appeared in major peer-reviewed journals. MarketScan data have supported a range of health services research conducted by government, academic and private researchers. These studies have been in the areas of:

- Economic burden of illness
- Clinical research
- Economic costs of health risks
- Health and workforce productivity
- Dental research
- Benefit plan design and adherence
- Adverse event rates
- Treatment outcomes
- Population studies
- Comparative effectiveness research
Limitations of the data
As with any data source, MarketScan data have limitations. Some limitations have to do with the nature of claims data and others with the nature of the MarketScan sample population. Key limitations include:

- The MarketScan claims databases are based on a large convenience sample. Because the sample is not random, it may contain biases or fail to generalize well to other populations. However, these data can complement other data sets or be used as benchmarks against them.
- Data come mostly from large employers; medium and small firms may be underrepresented, although the MarketScan warehouse does include a large amount of data contributed from health plans.
- Accessing the data requires data management software or programmer support.

Overview of MarketScan claims data

How the MarketScan data sets are built
Truven Health constructs the MarketScan claims databases by collecting data from employers, health plans and state Medicaid agencies who are our customers and have agreed to be data contributors to the MarketScan data warehouse. Data comprise service-level claims for inpatient and outpatient services and outpatient prescription drugs. All claims have been fully paid and adjudicated. We standardize financial, clinical and demographic fields and add contributor-specific fields. Drug detail (for example, therapeutic class, therapeutic group, manufacturer’s average wholesale price and a generic product identifier) and clinical detail (for example, disease episode grouper) are also added.

A unique enrollee identifier is assigned to each individual in a MarketScan claims database. This identifier is created by encrypting information provided by data contributors. We then combine the standardized fields of the individual databases and create links between years of data and across all data types. Data are collected for the MarketScan annual database releases when nearly 100 percent of claims have been paid; this eliminates the need for completion factors and improves the reliability and accuracy of the data.

Protecting the privacy of patient data, as well as the privacy of our customers, is a core principle of Truven Health. Therefore, the MarketScan Research Databases fully comply with the Health Insurance Portability and Accountability Act of 1996 (HIPAA). The MarketScan Databases meet the criteria for a limited-use data set and contain none of the data elements prohibited by HIPAA for such data sets. In addition, Truven Health has taken steps to go beyond these HIPAA requirements. The MarketScan Databases have undergone statistical analysis by a third party to verify that they meet HIPAA requirements for fully de-identified data sets. Although meeting these requirements is optional given the current MarketScan licensing process, this additional step demonstrates the Truven Health commitment to HIPAA compliance and to protecting the confidentiality of patient-level and
provider-level data. Finally, all patient-level and provider-level data within the MarketScan Research Databases contain synthetic identifiers to protect the privacy of individuals and data contributors.

We perform additional enhancements to the data during database creation. These include:

- Comparing diagnosis and procedure codes to codes that were in effect when the raw data were collected; editing the diagnosis and procedure codes, if necessary
- Adding major diagnostic categories (MDCs) and diagnosis-related groups (DRGs) to claims, along with the application of other classification systems, such as Outpatient Treatment Groups and Disease Staging
- Identifying the type of plan, such as health maintenance organization (HMO), preferred provider organization (PPO), and point-of-service (POS) or comprehensive plans
- Verifying that both the experience (claims) and the denominator populations (eligible enrollees) exist for data contributed to the database

The MarketScan warehouse:

**Fully integrated databases**

The end product is one of the largest collections of de-identified US patient data available for healthcare research, featuring:

- An opportunity sample from multiple sources (for example, employers, states and health plans)
- More than 32 billion service records
- Nearly 240 million covered lives
- More than 260 contributing employers and 40 contributing health plans
- Representation from more than 350 unique carriers

The MarketScan family consists of three core claims databases, a hospital discharge database and an EMR database, as well as several linked databases, data sets and files that combine claims data with other patient and employee data at the patient level, as illustrated in Figure 3.
The MarketScan Commercial Database consists of medical and drug data from employers and health plans. It contains data for several million individuals annually, encompassing employees, their spouses and dependents who are covered by employer-sponsored private health insurance in the US. Healthcare for these individuals is provided under a variety of fee-for-service (FFS), fully capitated and partially capitated health plans. These include PPOs and exclusive provider organizations (EPOs), POS plans, indemnity plans, HMOs and consumer-directed health plans (CDHPs). Medical claims are linked to outpatient prescription drug claims and person-level enrollment information.

The Commercial Database may offer a distinct advantage over other databases for research on medication use. As these data are primarily sourced from employers, claims for mail order prescriptions and specialty pharmacies are included to fully capture prescription fills from all locations. Comprehensiveness of drug data from all sources can be particularly important for adherence studies and analyses of injectable drugs.
Case study: Effectiveness of varicella vaccine

The US Centers for Disease Control and Prevention (CDC) have conducted a number of longitudinal studies to determine the impact of vaccines on overall healthcare utilization. Due to their size and robust longitudinal integrity, the MarketScan Databases may be ideal for studying the economic and utilization outcomes of treatment over time.

CDC researchers investigated the impact of the varicella (chickenpox) vaccine. Although the incidence of the disease dropped substantially since varicella was recommended for routine immunization in 1995, incomplete data made it difficult to track medical visits and expenses related to the disease. CDC researchers used the MarketScan Databases to conduct a retrospective, population-based study examining trends in rates and costs for varicella-related hospitalizations and ambulatory visits from 1994 to 2002. During this time period, hospitalizations related to varicella declined by 88 percent, and ambulatory visits declined by 59 percent. Total estimated direct medical expenditures declined by 74 percent, representing a savings of $62.8 million.

The MarketScan Medicare Supplemental Database was one of the first in the US to profile the healthcare experience of retirees with Medicare supplemental insurance paid by employers. The database includes the Medicare-covered portion of payment (represented as Coordination of Benefits Amount or COB), the employer-paid portion and any out-of-pocket patient expenses. The Medicare Supplemental Database provides detailed cost, use and outcomes data for healthcare services performed in both inpatient and outpatient settings. For most of the population, the medical claims are linked to outpatient prescription drug claims and person-level enrollment data through the use of unique patient or enrollee identifiers.

Beneficiaries in the Medicare Supplemental Database have drug coverage; therefore, drug data are available and provide additional valuable information. This feature makes the database a robust tool for pharmacoeconomic and outcomes research, and provides insight into the drug use and spending patterns of older Americans.

The MarketScan Medicaid Multi-State Database contains the medical, surgical and prescription drug experience of more than 44 million Medicaid enrollees from multiple states. It includes records of inpatient services, inpatient admissions, outpatient services and prescription drug claims, as well as information about long-term care and other medical care. Data on eligibility (by month), service and provider type are also included.
In addition to standard demographic variables, such as patient age and
gender, this database includes variables of particular value to researchers
investigating Medicaid populations, such as aid category (for example, blind
or disabled, Medicare eligible) and race.

Using this database alone or in conjunction with other MarketScan
Databases, researchers can:

- Analyze disease conditions that are especially prevalent among Medicaid
  populations, such as HIV/AIDS, schizophrenia and diseases of the elderly
- Assess trends in healthcare costs, utilization and outcomes for diseases
  that strike broadly across all populations, such as asthma, cancer and
  cardiovascular conditions
- Incorporate variables not available in other claims databases, such as race
  and aid category
- Determine the cost burden of particular diseases or conditions in Medicaid
  populations

The MarketScan Health and Productivity Management (HPM) Database,
an example of a linked database, provides the opportunity to combine
data on workplace absence, short- and long-term disability, and workers’
compensation with medical/surgical claims and outpatient drug data. The
database allows researchers to assess both the direct and indirect costs
associated with a particular condition or treatment.

Using the Health and Productivity Management Database, researchers can:

- Assess the direct and indirect costs associated with a clinical condition
- Measure the impact of diseases on absenteeism, short- and long-term
  disability, and workers’ compensation
- Track total healthcare costs across both medical and workers’
  compensation systems
- Estimate the potential return on investment in wellness or disease
  management programs
- Assess the impact of a child’s or spouse’s illness on employee absence
- Determine the relative costs of alternative pharmaceutical and medical
  device interventions, considering both group medical costs and
  absenteeism costs
- Develop predictive models that help define relationships between
demographic factors and HPM outcomes
Case study: Indirect costs for non-adherence in bipolar patients

Truven Health researchers examined the association between non-adherence to bipolar medications and lost productivity costs by employers. Adult patients with a bipolar diagnosis and at least one prescription claim for a mood stabilizer or atypical antipsychotic were selected for study.

In the selected cohort, only 35.3 percent of patients were adherent to their medication, as determined by a medication possession ratio of greater than or equal to 80. Non-adherent patients had higher adjusted indirect costs of $771.41 due to absence, $285.72 in short-term disability and $360.62 in workers’ compensation. Extrapolating these findings to a fictional employer with 70,000 employees and an incidence rate of 3.3 percent for bipolar disorder, this employer could potentially save $578,378 in combined absence, short-term disability and workers’ compensation indirect costs if all employee patients adhered to their bipolar treatment.

The MarketScan Benefit Plan Design (BPD) Database contains detailed information about benefit plan characteristics for a subset of the health plans represented in the Commercial and Medicare Supplemental Databases. This information, abstracted from summary plan description booklets, includes financial provisions, health service benefits, managed care features and health coverage types.

The Benefit Plan Design Database allows researchers to:

- Evaluate the impact of health plan features on healthcare utilization
- Assess the relative performance of plan types with varying managed care features
- Include detailed plan provisions, such as copayments, deductibles and coverage options in analysis of healthcare cost and use
- Measure changes in plan design and benefit characteristics from 1996 to the present
**Case study: Cost sharing and adherence**

Using patient-quarter data from the MarketScan Commercial Database, Truven Health researchers used generalized estimating equations to determine the effects of patient cost-sharing on adherence to second-generation antipsychotic medications. Results demonstrated that higher cost-sharing was inversely associated with high adherence, particularly when cost-sharing levels were above $30. Higher cost-sharing was associated with shorter time to discontinuation.

**The MarketScan Lab Database**, a linked claims-lab results database, includes inpatient and outpatient drug data, as well as enrollment and laboratory test results. In some diseases, results from clinical research are surrogate markers for risk reduction and disease management.

The MarketScan Lab Database helps researchers understand:

- How well a drug is performing in the real-world clinical setting
- Diagnostic test results administered prior to initiation of drug therapy
- Laboratory test results as indicators of drug therapy effectiveness
- Frequency of safety monitoring laboratory tests while a patient is on drug therapy
- Differences in treatment patterns between patients whose disease is under control versus not under control
**Case study: A1c monitoring in diabetes**

For diabetes patients to achieve and maintain control, the American Diabetes Association guidelines recommend that A1c tests should be repeated within three months following an out-of-range test result or a change in therapy. Truven Health researchers used the MarketScan Lab Database, which includes patients covered by both commercial and Medicaid insurance, to compare the frequency of retesting between groups of patients at varying A1c levels, based on an initial test. They also asked whether changes in therapy or insurance coverage were associated with more frequent retesting.

The results showed that retesting within six months is no more frequent after out-of-range tests or changes in therapy. In fact, retesting rates were lower for patients covered by Medicaid than for those with commercial insurance. Thirty-five percent of Medicaid patients with an initial A1c result of greater than 9 percent were retested, versus 51.7 percent of patients with commercial insurance. These results supported a previous finding of clinical inertia in response to poor glycemic control.

This study won an ISPOR Best Podium Award in 2007 at the 12th Annual International Conference.

**The MarketScan Health Risk Assessment (HRA) Database**, a claims-HRA linked data set, provides specialized data that allow researchers to understand the contribution of patient behaviors to health outcomes. HRAs can also be invaluable for researchers, as they provide self-reported data on clinical variables that may otherwise be unavailable. The HRA Database standardizes and links HRA data with the claims experience of patients; this feature presents an opportunity for innovative research. In addition to medical and drug claims, absence, short-term disability and workers’ compensation data, HRAs can provide key data inputs for analyzing the health and productivity of patient cohorts. There is significant overlap between the HRA Database and the HPM Database; this feature can enrich health and productivity management analyses. Researchers examining diabetes, cardiovascular disease, insomnia and smoking cessation may find these data valuable.
**Case study: The economic cost of obesity**

Self-reported data found in the HRA Database can help to identify the societal burden of obesity in the United States.

Truven Health researchers used MarketScan HRA and HPM data to quantify the direct and indirect costs of obesity to US self-insured employers. Body mass index (BMI) derived from HRA survey results allowed researchers to divide patients into risk groups, as defined by the CDC and the World Health Organization. Analysis of direct costs from claims and indirect costs from the same patients in the HPM Database yielded results that are consistent with previous research: Patients classified as obese or severely obese had higher overall healthcare costs. Overweight, obese and severely obese patients lost more work time than individuals with normal weight. This study provided payer cost estimates attributable to BMI categories.

**The MarketScan Dental Database** is one of the only integrated medical, drug and dental databases of its kind. This database links dental claims with medical claims, including the continuum of medical and dental care. It allows researchers to investigate the relationship between dental care, use of pharmaceuticals for oral health and patients’ medical conditions, such as:

- Respiratory tract infections
- Chronic sinus infections
- Diabetes
- Chronic acid reflux
- Liver or kidney problems
- Infective endocarditis
- Cardiovascular disease
- Preterm birth
Case study: Dental care and cardiovascular disease

Observational studies have suggested a relationship between cardiovascular disease and periodontitis caused by systemic inflammation that may impair the vascular system. In October 2008, the American Academy of Periodontology reported that patients with periodontal disease were twice as likely to have coronary artery disease as those without the disease.

Truven Health researchers examined the relationship between periodontal disease, statin (HMG-CoA) use and cardiovascular disease using the MarketScan Dental Database. Using a matched control group, patients identified as having periodontal disease by ICD-9 code or related dental procedures were divided into two cohorts: those treated with statins and those not treated with statins. The patients were followed for 12 months to observe evidence of cardiovascular events. There were no cardiovascular events in 99 percent of patients with periodontal disease. Twenty-five percent of patients with the disease were on statin medications. The rate of cardiovascular events for statin users and non-statin users were 0.42 percent and 1.16 percent, respectively. Controlling for differences in demographics and pre-existing clinical conditions, researchers observed that patients without statin treatment were at a greater risk for cardiovascular events than patients treated with statins in the 12 months following the periodontal diagnosis (OR = 2.77, 95 percent CI, p<0.0001).

The MarketScan Hospital Drug Database is derived primarily from hospital billing systems from US hospitals. This database provides some of the most detailed and comprehensive data available for understanding hospital care, including drug utilization in the inpatient setting.

The MarketScan Inpatient Drug Link File helps answer research questions regarding the effect of an inpatient stay on drug utilization. The file matches patients from MarketScan claims data (Commercial, Medicare Supplemental and Medicaid) and hospital discharge records (Hospital Drug Data). These data can help researchers understand:

- Drug use (spillover), switching and adherence between settings of care
- Pre- and post-hospitalization treatment
- Repeated hospitalizations
- Health outcomes
- Drug-specific and/or total healthcare costs
Claims data frame the picture of the continuum of care before, during and after hospitalization, thus providing rich cross-sectional and longitudinal details about patient treatment patterns (see Figure 4). Hospital discharge data provide the inpatient drug component. The result is enriched insights into the transition between inpatient and outpatient treatment.

**Figure 4. Tracking prescription drug treatment through a hospitalization**

The MarketScan Mortality File integrates death information with the enrollment and claims data for a subset of individuals who are found in the MarketScan Commercial and Medicare Supplemental Databases. The subset consists of individuals for whom a death could be ascertained. Individuals who died would have a month and year of death reported in this database; those who were alive during the time period of the database would have a missing date value. Death information allows researchers to evaluate mortality as a potential outcome in various studies, including:

- Safety and effectiveness research
- Evaluation of the healthcare delivery system and access to care
- Effectiveness of medical, drug and surgical interventions
- Economics of end-of-life care
- Population health trends and inequalities in care over time

Mortality information—in conjunction with other data elements available within the MarketScan claims data files, such as age, gender and diagnoses—provides researchers with a robust data asset that supports for age- and risk-adjusted mortality studies.

**MarketScan linked data:** Truven Health has deep experience in linking MarketScan administrative claims data to EMRs, patient registries, in-house customer and formulary data in a legally compliant manner. Our researchers have helped life sciences customers undertake unique linking projects using these data while maintaining scientific integrity, and Truven Health is the only company who can link the MarketScan Databases to other data.
Case study: Comparison of adverse events reporting between claims and EMR data

In this study, Truven Health researchers used multiple myeloma as a test case to understand the differences in the occurrence of selected adverse events recorded in an oncology EMR database compared with an administrative claims database. Further, they looked at the occurrence of selected adverse events in a linked claims-oncology EMR database.

A total of 278 patients met all study eligibility criteria. Patients were followed through their first line of therapy plus 15 days for the occurrence of selected adverse events including neutropenia, thrombocytopenia, venous thromboembolism (VTE), peripheral neuropathy and/or diarrhea. Adverse events typically monitored by oncologists either through routine laboratory values (for example, neutropenia or thrombocytopenia) or by direct observations during follow-up visits (for example, peripheral neuropathy) were recorded more often in the EMR. Adverse events such as VTEs often result in inpatient admissions and were more likely to be recorded in claims data. Conditions such as diarrhea, which may be due to a variety of causes including chemotherapy or general gastrointestinal illnesses, were recorded more often in claims data compared to the EMR. Overall, the analysis suggested that the linked claims-EMR database provided the more complete assessment of potential treatment-related adverse events and provided support for the utility of using a linked claims-EMR data source, such as the MarketScan Oncology Claims-EMR Linked Data Set, for oncology research.

Irwin DE, Varker H, Princic N, Farr A. Comparison of treatment-related adverse events recorded in administrative claims data with those recorded in electronic medical records for multiple myeloma patients. Truven Health Analytics. October 2015.
Additional data tools

Software tools and methodologies can be used with MarketScan data to increase analytic power or gain quick access to information. The MarketScan portal (marketscan.truvenhealth.com) includes the following tools.

**MarketScan Sample Select**
Sample Select provides quick access to MarketScan Commercial and Medicare Supplemental, Health and Productivity Management, and Health Risk Assessment data for querying counts of patient cohorts based on disease, diagnosis and/or procedures. This online tool enables researchers to quickly access patient population counts to assess research protocols and gather quick facts. Summary reports provide demographic, clinical and utilization details on the selected population.

**MarketScan Sample Select Prevalence**
Sample Select Prevalence uses the online Sample Select platform to quickly project the estimated prevalence of a treated condition or diagnosis among patients who are actively engaged in the US healthcare system and covered by employer-sponsored insurance—an estimated 49 percent of the total US population. Importantly, these estimates represent patients who are seeking care and covered by an important payer in the healthcare arena. Data come from the MarketScan Commercial and Medicare Supplemental Databases. Projections are based on the proprietary MarketScan weights.

**MarketScan Inpatient View**
Inpatient View, another online tool, uses a comprehensive catalog of all US hospital-based inpatient care to provide users with total diagnosis and procedure volumes and key statistics for the most recent year with trending information. For each diagnosis code, statistics include detailed patient demographics, admissions data, length-of-stay distributions, cost, regional and facility distributions, patient disposition and payer mix information.

Data are derived from all-payer data gathered from 23 million actual inpatient records, representing approximately 50 percent of discharges from US hospitals per year. This detail-rich database is the Projected Inpatient Data Base (PIDB)—a proprietary Truven Health database that is one of the largest all-payer inpatient database available. The PIDB supports publications, products and custom studies, the results of which are applicable to all short-term, general, nonfederal hospitals in the United States. This exclusive database combines public and proprietary state data, as well as individual and group hospital contracts.
**MarketScan Outpatient View**

Outpatient View details the total annual volume for diagnoses and procedures by outpatient setting: ambulatory surgery centers, outpatient hospitals and physician offices. Volumes are detailed by region, age, gender, outpatient setting and payer for the most recent year. Like Inpatient View, Outpatient View also provides a five-year forecast.

**Treatment Pathways**

Treatment Pathways is a visual interface into MarketScan or other research data that allows users to follow patients forward and backward in time throughout their courses of treatment. Results are obtained rapidly and without programmer support. Underlying Treatment Pathways are the medical, surgical, drug and lab data found in the MarketScan Databases. The software graphically represents the patient’s journey as a series of events that are sequenced into easily drawn treatment maps (Figure 5). Treatment Pathways may be used to understand events leading up to a diagnosis, time to treatment, switching patterns and treatment outcomes.

**Figure 5. Treatment Pathways increases the speed of analyzing MarketScan data**

Treatment Pattern Analysis allows users to identify and display multiple continuing patterns of drug and procedural treatments over time. The Pattern Transition diagrams show how users transition from one pattern of treatment to another over time. They can be put into motion with time animation to show the nonlinear flow of patients from one treatment modality to another (Figure 6).
Summary

The MarketScan Research Databases and online analytics tools offer comprehensive, flexible resources for life sciences research. The databases have several distinctive features:

- Integrated, patient-level data that are pooled from diverse points of care, reflecting the real-world continuum and cost of healthcare (including the indirect costs)
- Longitudinal tracking of patient data from all sources of care—one of the strongest in the industry
- Use of MarketScan data in more than 1,100 studies published in peer-reviewed journal articles places the MarketScan Research Databases among the most published in the United States

About Truven Health Analytics, part of the IBM Watson Health business

Truven Health Analytics®, part of the IBM Watson Health™ business, provides market-leading performance improvement solutions built on data integrity, advanced analytics and domain expertise. For more than 40 years, our insights and solutions have been providing hospitals and clinicians, employers and health plans, state and federal government agencies, life sciences companies and policymakers, the facts they need to make confident decisions that directly affect the health and well-being of people and organizations in the US and around the world. The company was acquired by IBM in 2016 to help form a new business, Watson Health. Watson Health aspires to improve lives and give hope by delivering innovation to address the world’s most pressing health challenges through data and cognitive insights.

Truven Health Analytics owns some of the most trusted brands in healthcare, such as MarketScan®, 100 Top Hospitals®, Advantage Suite®, Micromedex®, Simpler® and ActionOI®. Truven Health has its principal offices in Ann Arbor, MI, Chicago, IL and Denver, CO. For more information, please visit truvenhealth.com.

For more information

To learn how to obtain the MarketScan Research Databases for your healthcare research, please send an email to lifesciences@truvenhealth.com. Customized data sets and licensing agreements are available to suit specific data needs. For more information, please visit truvenhealth.com/life-sciences/marketscan.
